CICADAS OF THE GENERA OKANAGANA, TIBICINOIDES AND OKANAGODES, WITH DESCRIPTIONS OF SEVERAL NEW SPECIES.

By Wm. T. Davis,
New Brighton, Staten Island, N. Y.

The genus *Okanagana* probably contains more species of cicadas than any other in North America, and they are also in many instances quite hard to separate. In the northeastern part of the continent there appear to be only two species, but in the central and western parts it is far otherwise, and in California they are very numerous. As a rule the individuals of the same species resemble one another quite closely in color pattern, but occasional variation is seen, especially when the species is rather widely distributed. In his Preliminary Review of the West Coast Cicadidae, published in the *Journal of the N. Y. Entomological Society*, March, 1915, Mr. E. P. Van Duzee states that the "structural characters are very few in some of the genera, notably *Okanagana*, and I have been obliged to fall back upon color characters in the preparation of the key. The color and markings, while variable in extent, are quite constant in general facies for each species." A considerable number of species have been made known since 1915, but it will be some time before our collections are sufficiently complete to warrant the statement as to the exact number.

In considering the genus *Okanagana* it became necessary to first
identity Say's *Cicada rimosa*, described in 1830, and designated as
the type of his genus *Okanagana* by Mr. Distant in 1905. We hope
that we have successfully accomplished this, and the conclusions
reached are to be found in the remarks on *rimosa*.

The original description of the genus *Okanagana* was published in
the Annals and Magazine of Natural History, Seventh Series, Vol-
ume XVI, pp. 23, 190, 1905, and is as follows: “Head (including
eyes) considerably narrower than base of mesonotum and almost
equal to its length (including cruciform elevation); front shorter
than vertex, its apex more or less emarginate, vertex centrally sulcæ;
pronotum about as long as head, its anterior angles in a line with
eyes, its posterior angles dilated; abdomen in male longer, in female
about as long as space between apex of head and base of cruciform
elevation; tympana completely exposed, tympanal coverings entirely
absent; face more or less centrally sulcæ; rostrum reaching the
intermediate coxae; opercula small, transverse; abdomen beneath
with the lateral margins broadly recurved; tegmina and wings
hyaline; tegmina with the basal cell about or almost twice as long as
broad, apical areas eight; wings with six apical areas. Type, *O.
rimosa* Say (Cicada).”

The genus *Tibicinoides* was described by Mr. Distant in the An-
nals and Magazine of Natural History, Series 8, Vol. XIV, p. 166,
Aug., 1914, and Uhler's *Tibicen cupreo-sparsus* was designated as
type. Some of the characters mentioned are “tegmina and wings
semiopaque; tegmina with the basal cell about twice as long as broad;
apical areas short in length, eight in number, a curved rudimentary
vein, curved inwardly, crossing tegmen from base of first ulnar area
to base of lower apical area; posterior tibiae with a few fine spines.”
While the fore wings in *Okanagana mercedita* and *O. minuta* are not
colored as in *cupreo-sparsus*, the short apical areas show the three
species to be related, and they may in the future be placed in the
genus *Tibicinoides* as indicated in the table.

Owing to the length of the marginal cells Uhler’s *Cicada hesperia*
has been placed in the table near *striatipes* and *utahensis*, which it
also resembles in some other features, instead of in the genus
*Tibicinoides*, where its color pattern would place it.

In the table for the separation of species the natural sequence
could not be followed in every instance, but we hope that it will serve
to identify the members of this difficult group. In order to study
these Cicadas the specimens should be spread so that the venation,
the character of the basal cell of the fore wing and the color of the
basal membranes can be seen. If the wings on one side, preferably
the left, are expanded, it will suffice. Cicadas dry very quickly on
the stretching board and freshly captured individuals need remain
thereon only about a week, and those that have been relaxed in a
softening box a still shorter time. In *Tibicen, Cacama* and most of
the other genera of North American cicadas the uncus is withdrawn
by the insect into the abdomen, but in *Okanagana, Tibicinoides,
Clidoplopes* and *Platypedia* it is always exposed. Often it can be
fully examined without changing its position, but if the end be bent
downward and concealed by the valve, the uncus should be lifted up-
ward when the insect is mounted on the stretching board. A portion
of a match can be inserted with a forceps between the uncus and the
valve until the parts are dry, or the uncus may be simply lifted up
with a pin.

I have received important material from the following named
persons; other acknowledgments are made in connection with the
specimens recorded:

Dr. E. D. Ball, Dr. J. Chester Bradley, Prof. A. C. Burrill, Dr.
R. H. Beamer, Prof. W. H. Brittain, Prof. Robert A. Cooley, Alonzo
C. Davis, Emerson L. Diven, George P. Engelhardt, Prof. Frederick

davis: Cicadas.

DD. Outer edge of front wing of a more continuous curve.
Medium sized species, except schaeferi, which is large.
E. Legs almost entirely orange or greenish in color. Abdomen pale beneath including the rather long valve.

Pronotum mostly pale with a black median vitta gemmated anteriorly, the lateral oblique groves more or less broadly black. Two broad pale marks extending from the anterior extremities of the mesonotal X; a rather dull colored species with the uncus deeply cleft at extremity. Expands about 70 mm. ..........vandykei Van Duzee

Pronotum as in Vandykei; mesonotum reddish straw color, black centrally; tegrum black with posterior edge of the segments pale. A shining species with the uncus seen from above shallowly noticed at the extremity, and sinuate on lower margin when seen in profile. Expands a little over 60 mm. .................lurida new species

Head, pronotum and mesonotum almost entirely black, front margin of fore wing bright orange to the end of radial cell; basal cell opaque. Expands about 60 mm. .................ornata Van D.

Head, pronotum and mesonotum black, much variegated with dull orange; venation of fore wings uniformly light in color, basal cell clear; tegrum shining black with the segments narrowly margined with orange posteriorly. A larger headed species than the last, and with a shorter uncus. Expands about 60 mm. ..........napa new species

EE. Legs, especially the front pair considerably blackened.

F. Shining species with rather broad wings, and the hind margin of pronotum orange or reddish.
Front of head strongly produced; pronotum edged on sides and hind margin with orange, hind margin of abdominal segments both above and beneath orange. Last segments of abdomen beneath with short scattered pubescence. Expands about 75 mm. (Except in size this and fratercula resemble each other, and some specimens that may belong to the last named species are much larger than the type.) ..........schaefleri Davis

Venation of the fore wings fuscos, except the costal margin, which is often narrowly edged with black, but otherwise greenish-
orange to the end of the radial cell; subcostal vein black. Basal cell clear or nearly so. Pronotum edged on hind margin and at posterior angles and sometimes narrowly on sides with greenish-orange. Head small rather blunt in front, and proportionately broader than in the next species, very hairy on dorsal surface and with a considerable amount of rather long hairs behind the eyes; beneath thickly clothed with whitish hairs. Last ventral segment of female doubly notched. Expands about 60 mm. \textit{occidentalis} Walker

Of a slightly bluish tint, otherwise colored about as in the last species, but the costal margin of the fore wings to the end of the radial cell often bright orange, the basal cell clouded sometimes blackened. Pronotum usually plainly edged with orange on sides as well as on hind margin. Head not as blunt when viewed from above as in \textit{occidentalis}, proportionately narrower and with little hair behind the eyes, also less hairy beneath. Last ventral segment of female not doubly notched, or second notch but feebly indicated. Expands about 60 mm. \textit{bella} new species

\textbf{FF.} Dull bodied species or at most feebly shining, with proportionately narrower wings, and the hind margin of pronotum orange or reddish, except in \textit{tristis} where it is black. Dorsum of the abdomen often with conspicuous transverse rows of short silvery hairs.

Basal cell of fore wings slightly clouded, pronotum blackish mottled each side with testaceous, the hind margin and sides reddish. Tergum with the posterior edges of the segments reddish, the vestiture more sparse than in \textit{canadensis} and more in the nature of hairs. Expands about 60 mm. \textit{rimosa} (Say)

Venation of the fore wings often thickened; basal cell clouded and blackened. Pronotum usually entirely black, except the hind margin which is testaceous, sometimes clouded each side with reddish; tergum black with much tomentum, which when removed leaves a smooth surface. A black species with the usual four orange spots before the mesonotal X, and orange membranes at the base of both pairs of wings. Expands about 62 mm.

\textit{canadensis} (Provancher)

Venation about as in \textit{canadensis}, but the veins not thickened. Pronotum generally all black, but sometimes mottled with dull red each side of the center. Further distinguished from the other two species in this section by having the abdomen beneath centrally pale. Expands about 70 mm.

\textit{tristis} Van D.

\textbf{CC.} Base of the fore and hind wings not of the usual orange red variegated with black.

Color rufo-ferruginous including the venation of fore and hind wings, with a few marks on the vertex and a dorsal vitta on the tergum black. Expands about 70 mm.

\textit{arctostaphyloides} Van D.

Body almost entirely black; basal cell of the fore wings clear; membranes at base of both pairs of wings whitish. Expands about 65 mm. \textit{canescens} Van D.

Body and wing venation nearly entirely green; basal cell of fore wings clear. Expands 65 mm. \textit{viridis} Davis

Body and wing venation nearly entirely orange; basal cell of fore wings clear; a black band between the eyes, and a conspicuous dorsal band of the same color extending from the hind margin of the pronotum to the end of the abdomen. Expands about 55 mm. \textit{aurantiaca} Davis

\textbf{BB.} Expanse of fore wings 50 mm. or less; orange variegated with black at base of both pairs of wings. (Some examples of \textit{fratercula} exceed 50 mm.)

\textbf{G.} Pronotum in mature individuals black centrally margined with orange especially behind. In \textit{triangulata} the grooves of the pronotum are sometimes orange colored.

Basal cell of fore wings darkly opaque, abdomen black beneath with hind margins of segments reddish. A dark colored species. Expands about 47 mm. \textit{fratercula} Davis

Basal cell and venation of fore wings yellowish; abdomen yellowish beneath with numerous silken hairs; front of head and eyes not prominent. Expands about 50 mm.

\textit{oregona} Davis

Basal cell of fore wings translucent; abdomen yellowish be-
neath with silken hairs very short or absent; front of head and eyes prominent. Expands about 50 mm.

**triangulata** Davis

**GG.** Pronotum in mature individuals black with the central portions variegated with orange or yellow. Basal cell of fore wings yellowish or translucent.

Head small, front prominent; discal yellow marks extending from the mesonotal X to the front margin of the mesonotum. The veins surrounding the first seven marginal cells of fore wing infuscated. Expands about 42 mm.

**synodica** (Say)

Membranes at base of fore and hind wings pinkish, remainder of wing venation yellowish. The W mark on the front portion of the mesonotum separated from the mesonotal X; tergum darker, the terminal segments nearly all yellow as in **synodica**. Expands about 46 mm.

**balli** new species

**AA.** Male uncus hooked at extremity.

**B.** Rather slender bodied species with the venation of fore and hind wings colored almost uniformly throughout.

Black clothed with minute dark rufus hairs giving the insect a dull reddish aspect. Expands about 55 mm.

**rubrovenosa** Davis

**BB.** Stouter bodied species, the fore and hind wings variegated with orange and black at the base.

**C.** Third marginal cell more than one half as long as second ulnar area adjoining and immediately behind it.

**D.** Expand about 55 to 60 mm. Black species with basal portions of fore and hind wings orange variegated with black.

**E.** Front of head not conspicuously produced; under side of abdomen with very numerous long silken hairs.

**F.** Abdomen black above or nearly so in var. **californica**.

Almost wholly black above, pronotum dull rufus, particularly on the sides; abdomen beneath with the central area black, except the reddish or yellowish posterior margin of each segment; valve black on under side. Expands about 60 mm.

**vanduzeei** Distant

Dorsal markings much lighter, especially about the mesonotal X; abdomen beneath with a black spot on each segment except

**Davis:** Cicadas.

the last. Expands about 55 or 60 mm.

**vanduzeei** var. **consobrina** Distant

Dorsal markings of the pronotum still more extended and confluent; beneath, abdomen almost entirely yellowish, valve yellowish. Expands about 57 mm.

**vanduzeei** var. **californica** Distant

**EE.** Front of head conspicuously produced; silken hairs on under side of abdomen short and inconspicuous.

Dorsal surface with much appressed golden pubescence; abdomen black and yellowish above, and usually entirely yellowish beneath. Basal cell usually transparent. Expands about 53 mm.

**striatipes** (Haldeman)

Dorsal surface with the hairs more upright than in **striatipes**, which it much resembles in markings. Dorsum of abdomen black, beneath central area usually black with hind margins of segments reddish. Basal cell darkened. Expands about 60 mm. . . . utahensis new species

**DD.** Expand about 52 mm, usually much less.

**G.** Fore and hind wings, except marginal cells, infuscated. Uncus when viewed from behind with hook terminating in a broadly rounded notch. Expands about 52 mm. . . . . . . . . **hesperia** (Uhler)

**GG.** Fore and hind wings clear except at extreme base, where the membranes are orange.

**H.** Yellowish or yellowish green; front conical and prominent. Expands about 50 mm.

**pallidula** Davis

Smaller and darker than the last; head small; front not so prominent. Venation approaching the next two species. Expands about 48 mm.

**uncinata** Van Duzeé

**CC.** Marginal cells short; the third one in fore wings about one half as long as second ulnar area adjoining and immediately behind it.

**H.** Both pairs of wings clear except near base.

Head including eyes about 5 mm. broad. Expands about 40 mm. . . . . . . . . . **mercedita** Davis

Head including eyes about 4 mm. broad. Expands about 35 mm. . . . . . . . **minuta** Davis

**HH.** Both pairs of wings clouded, particularly the basal half of front pair.

Head including eyes about 4.5 mm. broad, membranes
at base of both pairs of wings vermilion; tergum black. Expands about 34 mm.

Tibicinaoides cupreo-sparsus (Uhler)

In addition to the species mentioned in the key there are two others of which only the female sex is known. Okanagana hirsuta Davis was described and figured in the Journal of the N. Y. Entomological Society for March, 1915, from a specimen in the collection of the American Museum of Natural History, labeled Santa Rosa Island, California. It expands about 80 mm., and resembles a greatly enlarged vanduscei, but it is even more hairy beneath than in that species; the front of the head is not quite as rounded, and the basal cell of the fore wing is clear instead of clouded as in vanduscei. Unfortunately in the original description the width of the fore wing in hirsuta is printed 7 instead of 11 mm. The insect is shown correctly in the figure.

Okanagana rotundifrons Davis was described and figured in the Journal of the N. Y. Entomological Society for September, 1916, from a female in the collection of the University of Kansas taken in Arizona. It expands 71 mm., and is a shining black and yellowish species, with a conspicuously blunt and rounded front.

Okanagana cruentifera (Uhler). Pl. xix. fig. 2.

In the United States National Museum there is a female from "F. H. Hillman, Reno, Nev. 6, 21, 1890," labeled "Tibicen cruentifera Uhler, Cotype from Uhler’s Coll." in the handwriting of Mr. Heide-mann. No label by Uhler is on the specimen. It is spread; expands 75 mm., with the front of the head quite prominent, and the notch in the last ventral segment double. According to the original description all of the cotypes came from Nevada. Another specimen in the Uhler collection, captured after cruentifera had been described, is labeled "F. H. Hillman, Reno, Nev. 7, 3, 98," and identified as "Tibicen cruentifera Uhler, Nev." in Uhler’s handwriting. This is a spread specimen, expands 78 mm.; front is prominent; the pronotum is almost entirely black, with a hair line of red along the hind margin; venation about the marginal cells not clouded.

A male in the U. S. National Museum is labeled simply "Nev.," and on a separate label "P. R. Uhler collection." This may be one of the cotypes. It expands nearly 70 mm.; head and pronotum entirely black, grooves containing much pubescence; mesonotum with the usual discal reddish spots, hind margin red; tergum with posterior margins of the segments red; fore wings with the costal margin orange to the end of the radial cell, darker beyond; first and second cross veins not infuscated; basal cell clouded; membranes at base of both pairs of wings of a bright red. Beneath femora dull red variegated with black especially at the ends; under side of abdomen black with the posterior margin of each segment rather broadly and unevenly margined with red; valve light colored. We present a figure of this specimen.

In the American Museum of Natural History there are three females from Nevada, one of them labeled Virginia City, like the one described above. They expand from 70 to 75 mm.

Lately we have received a female collected June 25, 1919, and a male collected June 27, 1919, at Coal Creek, Iron Co., Utah, by Mr. Tom Spalding.

Four males labeled Los Angeles Co., Cal., July, Collection Co- quillet, are in the United States National Museum and are like the Nevada male described above. Two males from Nellie, Calif., June 20 and 24, 1918 (E. P. Hewlett), are in the writer’s collection and are darker than the other specimens here mentioned, with the costal margin of the fore wings not as brightly colored and edged with a narrow line of black. The membranes of both pairs of wings are blood red at base as in true cruentifera. The tergum is nearly all black, while beneath the abdomen and valve are shining red, the former blackened along the sides and at base. Expand 70 mm. This seems to be a variety of cruentifera.

Okanagana magnifica new species. Pl. xix, fig. 1.

Type male from Jemez Springs, New Mexico, June 4, 1918 (John Woodgate), and allotype female from same place, July 1, 1918, Davis collection.

Resembles O. cruentifera, but is larger and has differently shaped uncus.

Head slightly narrower than the front margin of the pronotum; front moderately protruding and covered with long grayish hair, face also very hairy. Median sulcus of the front well defined. Pronotum with the humeral
angles rounded, the anterior angles not very prominent and almost hidden by long hairs from behind the eyes and growing on the pronotum itself. Last ventral segment slightly constricted at the sides, then broadened out to the extremity, which has the outer angles rounded; not sinuate at extremity. Uncus when viewed in profile elevated centrally with a slight sinuation near

Okanagan Magnifica

the lower extremity; when viewed from behind, notched at the extremity, and more deeply so than in *cruentifera*. The valve in the male is long and orange in color. The last ventral segment in the allotype is simply and broadly notched; the notch is double in *cruentifera*. Fore wings with the costal margin bright orange nearly to the extremity of the wings, the remaining veins fuscous, somewhat thickened and clouded at the marginal cells; basal cell blackened; membranes at base of both pairs of wings of the brightest orange; not blood-red as in *cruentifera*. Head entirely black; in some of the paratypes the antennae are marked with orange on the basal joint. Pronotum entirely black in the type; in the allotype it is very narrowly edged posteriorly with red. Mesonotum red at the sides, otherwise black including the X. Metanotum edged posteriorly with red. Tergum black with the first six segments edged with red at extreme lower part of the sides only, segments seven to nine edged completely on the posterior margin with red. Beneath the body including the legs hairy; the legs are orange-red striped with black and the abdominal segments more evenly edged posteriorly with orange-red than in *cruentifera*.

In addition to the type and allotype I have received sixty-two males and eighty-nine females collected at Jemez Springs, New Mexico by John Woodgate at 6,400 ft. to 7,500 ft. elevation, June 2 to July 2, 1918. They were most common about the middle of June. Mr. Woodgate writes that the "Navajo children tear the legs and wings off of the cicadas and eat them—say they taste like pecan nuts."

The species must have been quite plentiful in 1918 in parts of New Mexico, for Mr. Warren Knaus sent me a male and female collected about four miles southeast of Santa Fe, on the old Santa Fe trail on scrub pine and cedar, June 15, at an altitude of about 7,000 feet. In 1919 Mr. Woodgate collected seventy-eight specimens of this species at Jemez Springs. Mohave Co., Arizona, 1919, 3 males, 4 females.

In the United States National Museum there is a male *magnifica* labeled "*Tibicen cruentifera* Uhler var. Uhler," from "E. A. Bush, San Jose, Cal., Aug. 2, 1887." Evidently Uhler himself considered this not a true *cruentifera*. Two other specimens are as follows: a female from "Nordhoff, Cal., 4, 6, 1905, W. M. Slosson," expands 88 mm., last ventral segment with notch simple; male "From W. M. Slosson, Nordhoff, Cal., June 4, 1905, found on pinon trees near the west end of San Emedio Mts., Cal." The male bears a further label by Mr. Heidemann, "*Tibicen cruentifera* Uhler var." Also in the U. S. National Museum there is a female from "Nucla, Cal. Ch. T. Trueb, Sept. 7, '09," with a slightly smaller head than the Nordhoff female. It expands 88 mm. and the last ventral segment is simply notched. It is labeled "*Fidicina cruentifera* Uhler, O. H."

**Okanagan mariposa** Davis.

The type of this species came from Mariposa Co., California, June 16, 1914. In the collection of the United States National Museum there is a male also from Mariposa Co., Calif. It has been compared with the type and is like it in every particular, except that it is larger, expanding 90 mm. Lately Dr. F. E. Blissdell has sent to me two males and a female collected by him at Hullville, Lake Co., Calif., June 13, 1917. The female is the first one I have seen and is colored, as are the two males, almost exactly as in the male type. The size is very nearly the same. Beneath the notch in the last ventral segment is remarkable for its great breadth; at its central portion there
is a minute situation just opposite the ovipositor. The straight outer margin of the fore wings and the broad head with slightly protruding front, are conspicuous features of this large species.

A male and female collected at Bellevue, Washington Co., Utah, June 21, 1919 (Tom Spalding) are like the specimens examined from California.

Okanagana vandykei Van Duzee.

Reported in the original description from Carrville, Trinity Co., Calif., June 29, 1913; Nash Mine, Trinity Co., Calif., June 29, 1913, 8,000 ft., and Plumers Co. Calif., June. To these records may be added a female from Keddie, Plumas Co., Calif., June 7, 1918, 3,500 ft. (F. M. Jones), Davis collection. We have examined a male from

Riddle, Oregon, June 18, which is like the paratype from Plumas Co., with the same long, orange colored valve, orange marks on pronotum, etc., except that the front is more prominent and black. A female from Forest Grove, Oregon, July 30, 1917 (Catherine Jones collector), has the body colored as usual, but the costal margin of the fore wings to the end of the radial cell is bright green instead of the more usual orange. The first anal vein is also bright green, and the basal cell is darkened along the hind margin.

Okanagana lurida new species. Pl. xix, fig. 3.

Resembles Okanagana vandykei in color but has less dark markings, and is more shining. The uncus is not as deeply cleft at extremity as in that species. It is probably generally smaller, judging from the type.

Head slightly narrower than the front margin of the pronotum;

front moderately produced. Median sulcus of the front not very deep. Pronotum with the humeral angles rounded, the lateral edges rather rough and uneven, and the anterior angles prominent. Last ventral segment hardly constricted at the sides, but evenly narrowed to the extremity, which is almost truncate. Uncus when viewed in profile sinuate on lower part with the greatest depth beyond the center; when viewed from behind shallowly notched. Fore wings with the vena- tion almost entirely straw colored; the veins about the marginal cells are fuscous, and the basal cell is clear or nearly so. The membranes at the base of both pairs of wings are bright orange. Head reddish straw-colored with a short irregular blackish mark each side of the central ocellus, and a blackish dot between each hind ocellus and the eye. Front and the transverse rugae black. Pronotum reddish straw-colored with a central band, narrowest in the middle, black; also blackened irregularly in the grooves, and a submarginal black band posteriorly and on the sides. Mesonotum almost entirely reddish straw-colored; the region covered by the W mark blackened; and an irregular central black band extending from thence to the elevated X, which is pale, but the adjoining depressions are black. Metanotum reddish straw-colored, with a submarginal blackened area. Tergum black, with each segment reddish strawcolored posteriorly.
The uncus is black. Beneath the legs are almost entirely light in color blackened at the knees, the abdominal segments are covered with much short hair; are reddish straw-colored margined anteriorly with red. In addition each segment has two dark colored basal blotches more or less connected, one each side of the center. The valve is dark colored on the lower surface, lighter near the upper margins, and when viewed in profile it does not extend as far beyond the end of the uncus as it does in *vandykei* and *ornata*.

**Okanagana ornata** Van Duzee.

In the collection of the American Museum of Natural History there is a male labeled "Nevada." We have also examined a male from Hood River, Oregon, June 10, 1916, in the collection of the Oregon Agricultural College, and a female from Blue Canyon, Calif., June 7, 1909 (Ball), in the collection of Dr. E. D. Ball. In the writer's collection there are two males and one female from Sonoma Co., Calif., one of the former being the allotype of the species, and a male from Keddie, Plumas Co., Calif., June 28, 1918, 3,500 ft., collected by Mr. Frank M. Jones of Wilmington, Delaware, who kindly presented it to me. This is a very bright and contrastingly colored species. Mr. Van Duzee states "This species may be recognized by its black, almost immaculate upper surface with bright orange venation."

**Okanagana napa** new species. Pl. xix, fig. 4.

Resembles *Okanagana ornata* in size and in being shiny, but is lighter colored, has a larger head and a shorter uncus.

Head quite broad and nearly of the same width as the front margin of the pronotum; front not prominent; median sulcus well defined. Pronotum

with both the humeral and anterior angles rounded, the latter much more so than in either *lurida* or *ornata*. Last ventral segment gradually narrowed to the extremity which is situated with the angles much rounded. Uncus when viewed in profile short with the lower side much straighter than in *lurida*; when viewed from behind, shallowly notched. Fore wings with the venation almost entirely straw colored, slightly darkened about the marginal cells; the basal cell is clear. The membranes at the base of both pairs of wings are orange, but these as well as the venation, lack the bright color of *ornata*. Head black with the grooves, front and the region of the transverse rugae almost wholly dull orange. There is a broken black band consisting of four spots extending across the front, and the hollows between the transverse ridges are narrowly lined with fuscous. The terminal part of the rostrum is black, the base is pale. Pronotum black centrally, but margined all round except at the anterior angles with dull orange, and the orange of the grooves considerably spread. This leaves only the central part black, with some irregular black marks on the ridges between the grooves, and a submarginal black band along the sides and posterior margin. Mesonotum dull orange with four oblong black marks on the anterior margin, and a central spear-shaped mark extending toward the orange elevated X. There is a black dot each side at the anterior extremities of the X, also an interrupted black band extending each side from the X to the base of the fore wing. Metanotum edged posteriorly with orange. Tergum shining black, with the segments narrowly edged posteriorly with orange. The uncus is black. Beneath the legs are light colored except at the knees and the fore femora are somewhat blackened on the inner side; the abdomen is light, except the usual dark spot centrally near the base, and the valve is also light in color.

Okanagana schaefferi Davis.

This species was described from a single male in the collection of the Museum of the Brooklyn Institute of Arts and Sciences, from Iron Co., Utah, 1904. In June, 1917, Mr. George P. Engelhardt of the Brooklyn Museum collected a number of specimens in the foot hills of the Kolob Mts., Washington Co., Utah, and kindly gave me seventeen males and two females. Other specimens examined have been a male, Manti, Sampete Co., Utah, June 23, 1903, collection Dr. E. D. Ball, a male from Salida, Colorado, June, 1885, collection University of Nebraska, and a female from Jemez Springs, 6,400 ft., New Mexico, June 17, 1919 (J. Woodgate). A noticeable feature of this large insect is the strongly protruding front of the head.

Okanagana occidentalis (Walker).

This species was listed as a synonym of rimosa Say by Distant in his Synonymic Catalogue of Homoptera (1906), but it is distinct from that species, and from Okanagana bella described in this paper, which it more closely resembles. The most noticeable differences between these three species have been mentioned in the table, and in series occidentalis is not as blue-black as bella, and the pubescence on the upper surface is more abundant and more golden in color. The true rimosa is a duller colored insect, the tergum not shining as in occidentalis and bella. Walker's description is poor and we may be in error in applying it to this species. The description would also apply to some specimens of vanduzei except that they are usually too small. He states that the body is, 12 lines in length, is black, and that the mesothorax has two V-shaped testaceous marks, "which extend from the fore border to the disk, and are distinct except at the tips." These V-shaped marks are commonly present in what we have called occidentalis, and the tips are usually well defined. In bella the V-shaped marks are obscure or absent.

John Keast Lord in The Naturalist in Vancouver Island and British Columbia, has this to say of this species: "But there was one sound—song perhaps, I may venture to call it—that was clearer, shriller and more singularly tuneful than any other. It never ap-
July, 1917. The specimens of this long series are uniform in appearance, they are black above with the hind margin of the pronotum orange, four orange spots arranged in a semi-circle before the mesonotal X, and the X itself with the elevated parts touched with orange. The basal cell of the fore wing is clear. The last ventral segment in the females is doubly notched.

**Okanagana bella** new species. Pl. xx, fig. 1.

Type male from Stockton, Utah, June, 1915, and allotype female from Soldiers' Canyon, Stockton, Utah, June 27, 1915 (Tom Spalding). Davis collection.

Resembles **Okanagana occidentalis**, but differs as indicated in the remarks on that species, and in the characters given in the table.

Some of the paratypes represent a darker race, blacker on the legs, and in the fore wings the costal margin is not as conspicuously orange.

This insect has generally been considered the Cicada rimosa of Say, but that species is duller colored and appears to be more eastern in its range.

The following specimens of **Okanagana bella** have been examined:

Utah.—Logan, June 10, 1904, male; July 4, 1904, two females; June 22, 1906, four males, two females; Logan Canyon, June 19, 1909, three males and two females; July 4, 1909, two females, from collection Dr. E. D. Ball. Garland, June 11, 1904, male; June 18, 1904, male and two females, collection Dr. Ball. Wellsville, July 3, 1904, female, collection Dr. Ball. Salt Lake City, June 8, 1902, male, and June 15, 1902, male, Davis collection; male and two females without date labels (Dr. Henry Skinner), collection Acad. Nat. Sci., Philadelphia. Silver Lake, July (Dr. Skinner), collection Acad. Nat. Sci., Philadelphia. Mill Creek, June 20, 1906, two females (E. G. Titus),
Dr. Ball collection. Stockton, June, 1915, three males (Tom Spalding), and Soldiers' Canyon, Stockton, June 27, 1915, three males and two females (Tom Spalding), Davis collection. Santequin, male and two females (T. H. Parks), Davis collection. Provo, June 3, 1910, female; June 4, 1910, two males; June 24, 1912, two males and two females (Spalding), Davis collection. Eureka, June 19, 1910, female (Spalding), Davis collection. Nephi, June 25, 1912, male, collection Dr. Ball. Cedar Mountains, Iron Co., 8,500 ft., July 11, 1917, seven males (Geo. P. Engelhardt), Davis collection. Kolob Mountains, Washington Co., 8,500 ft., June 30, 1917, eight males (Geo. P. Engelhardt), Davis collection.

Kansas.—Male and female with no date label, collection Acad. Nat. Sciences, Philadelphia.

Colorado.—Livermore, July 8, 1900, two males, collection Dr. Ball. Ft. Collins, June 29, 1901, two males and three females, collection Dr. Ball. Estes Park, male, collection Univ. of Kansas. Golden, June 26, 1911, male (C. A. Frost), Davis collection. Russell, June 24, male (H. S. Smith), Davis collection. Creede, 8,844 ft., Aug., 1914, female (S. J. Hunter), collection Univ. of Kansas. Durango, August 1, 1912, male (Oslar), Davis collection.

Wyoming.—Newcastle, male and female, collection Univ. of Nebraska. Yellowstone National Park, June 20, 1907, male; June 30, 1907, female; July 9, 1907, female (Col. Wirt Robinson), Davis collection.

Idaho.—Whitebird, June 29, 1907, male (Dr. J. M. Aldrich). Moscow, June 13, 1911 (Dr. J. M. Aldrich). Both of these records are from specimens in the collection of the University of Idaho.

California.—El Dorado Co., July, 6,280 ft., male (Dr. F. E. Blaisdell). Moneacree Meadows, Tulare Co., 8,000 ft., July 17, 1917, male (G. R. Pilate). Top of Mt. San Antonio, 10,000 ft., Southern Calif., June 29, 1914, female (H. Newcomb). San Antonio Canyon, Ontario, July 25, 1907, male and female, Coll. Ohio State Univ. In these and some of the Oregon examples the basal cell of the fore wings is almost entirely black.

Lately Mr. L. P. Rockwood sent me for examination five males and one female collected at Baker City, June 17, 18 and 24, 1917, which have very dark colored bodies, the tergum showing but little red on the edges of the segments at the sides, the basal cell is nearly black; the anal membranes are vermillion and the costal margin of the fore wings is bright orange to the end of the radial cell. He also sent to me two males and a female collected by C. W. Creel, at Paisley, Lake Co., south central Oregon, on the borders of Chewaucan Marsh.

Alberta.—Jasper, July 4, 1915, two males, collection Cornell University and Davis collection.
British Columbia.—Male without any date labeled “Brit. Col. (G. W. Taylor),” Davis collection. Lillooet, July 6, 1918, male (A. B. Baird), Baird collection.

**Okanagana rimosa** (Say). Pl. xx, fig. 2.

1854. Cicada noveboracensis Emmons, Nat. Hist. N. Y. Ins., p. 152, pl. 9, fig. 6.

The principal characters given in the original description are:

"Body black above, . . . a rufus spot over the antennae; thorax obso-
letely varied each side with picceus; posterior and lateral edges rufus:
scutel with the elevated cruciform line, two spots before it, and two or three on each side rufus: . . . tergum, posterior edges of the seg-
ments rufus: beneath rufus, varied with black: . . . length to the tip of
the hemelytra one inch and one-fourth." Say further adds: "Mr. Nuttall presented me two specimens, which he obtained on the Mis-
souri, and I found one on the Arkansaw"; also: "On the prominent
middle of the hypostoma is a very obvious impressed line."

The insect which he collected "on the Arkansaw," when he was
with Major Long's expedition to the Rocky Mountains in 1819-1820,
may not have been the same species as the two specimens mentioned
first in the description and given to him by Nuttall, who obtained
them along the Missouri River.

It next becomes important to ascertain, if possible, from what
locality the type specimens of Cicada rimosa were obtained, and I have
been to some pains to look up the original authorities. As an aid to this Dr. N. L. Britton, of the New York Botanical Garden,
has sent to me some notes by Dr. P. A. Rydberg on the three journeys
made by Thomas Nuttall, the botanist, to regions west of the Mis-
sissippi. It was on the first of these, namely in 1811, or Astoria ex-
pedition, that he collected the two specimens referred to, for the very
good reason that in the second expedition of 1819-1820, he went along
the Arkansas River, and did not touch the Missouri; and the third
expedition started in 1834 after Cicada rimosa had been described.

John Bradbury, another botanist, was with the Astoria expedition,
and in 1817 he published in London, England, a narrative of his trav-
els in the interior of America. He and Nuttall accompanied Mr.
Hunt from St. Louis up the Missouri as far as the Arickara Indian

village in the north central part of the present South Dakota, and in
late June they both went about 150 miles still further north to the
Mandan Indian village close to the site of the present city of Bis-
mark in North Dakota, where they stayed for a few days before re-
turning to the Arickara village. In Bradbury's account we read on
page 226 the following from Mr. Cook's narrative of Mr. Hunt's expe-
dition from the Aricarara to the Pacific. "Messrs. Hunt, Crooks,
Miller, M'Clellan, M'Kenzie, and about sixty men, who left St. Louis
in the beginning of March, 1811, for the Pacific Ocean, reached the
Aricara village on the thirteenth day of June. . . ." Mr. Crooks was
one of the partners and we quote his statement to show, among other
things, that it was 1811 and not in 1810, as has sometimes been stated,
that the Astoria party ascended the Missouri. From reading Irving's
account one might easily get the impression that it was in 1810.

Irving in his Astoria says: "On the 18 of July Mr. Hunt took up
his line of march by land from the Arickara village leaving Mr. Lisa
and Mr. Nuttall there where they intended to await the expected ar-
ival of Mr. Henry from the Rocky Mountains. As to Messrs. Brad-
bury and Breckenridge they had departed some days previously on a
voyage down the river to St. Louis, with a detachment from Mr.
Lisa's party."

Mr. Bradbury records that he started on July 17, and it took him
until the end of July, or slightly longer, to reach St. Louis, and on
page 193 he further states that Mr. Lisa with whom Nuttall had re-
mained, arrived in St. Louis in November.

From the foregoing it will be seen that Cicada rimosa was no
doubt taken close to the Missouri River in what is now North or
South Dakota, for Mr. Nuttall did not arrive at the Aricara village
until about the time the species of Okanagana emerge, and allowing
him a month or more to reach St. Louis, he left the Indian village
after their season was over.

We now know that there are several species of Okanagana that
resemble rimosa and may be mistaken for it, but having located Mr.
Nuttall's whereabouts in June, July, August and September, 1811,
covering the time of emergence of these insects, we can more cer-
tainly identify the species by our examination of specimens from the
same region. This has been done and a male collected at Sioux City
on the Missouri by A. W. Lindsey, and presented to me by Prof. H. F. Wickham, has been identified as *Okanagana rimoso*. This insect fits Say's description in every particular. The uncus is slightly more pinched or ridged on the dorsum, also the cleft at the extremity is somewhat deeper than in the males of *Okanagana novoboracensis* (Emmons) from New York and Maine, but in other particulars it appears to be the same. It is probable therefore that *novoboracensis* is the same as *rimosa*, certainly not more than a variety.

The fore wings in *rimosa* and *canadensis* (Provancher) are proportionately narrower than in any of the other species considered and in this particular the two Okanaganas that extend to the northeastern United States and eastern Canada, can thus be separated from the more western forms, *tristis* Van Duzez, excepted.

In addition to the Sioux City example already referred to, the following specimens have been examined:

Minnesota.—Itasca, July, 1908, female, and male and female labeled simply “Minnesota,” collection University of Minnesota.

Wisconsin.—Bayfield, female (Prof. H. F. Wickham), Davis collection.

Manitoba.—Aweme, June 19, 1917, two males (N. Criddle), Davis collection. Treesbank, July 7, 1907, male, and June 11, 1914, male (N. Criddle), Davis collection.

Ontario.—Toronto, June 19, 1896, female, collection Dr. E. D. Ball.

Illinois.—Ogle Co., male (Uhler collection), U. S. Nat. Museum.

Quebec.—Kazubazua, Ottawa District, July, 1917, male, collection C. B. Gooderham.

Pennsylvania.—Cresco, Monroe Co., June 9, 1918, female (J. N. Knoll), Davis collection. Echo Lake, Pike Co., July 8, 1910 (E. Shoeemaker), Davis collection.

New Hampshire.—Chocorua, August 12, 1917 (Linder), Boston Soc. Natural History.

Nova Scotia.—Truro, July 5, 1913, male (L. G. Saunders), Saunders collection.

The song of this species continues for some time and somewhat resembles the sound produced by *Neconocephalus retusus* or *N. robustus*, two of the large, long-horned katydid-like insects. Though we have not been able to collect them, we have heard cicadas of the genus *Okanagana* singing on Crow's Nest Mt., West Point, N. Y., on June 15, 1913, and again on June 13, 1914, and Col. Wirt Robinson collected a pupa-skin on the same mountain. We have also heard them singing in Letchworth Park, Portage, N. Y., June 13, 1915; near Potter's Swamp, Yates Co., N. Y., June 14, 1915, and in Egleston's Glen on the east side of Lake Keuka, N. Y., June 15, 1915.

*Okanagana canadensis* (Provancher). Pl. xx, fig. 3.

1889. Petite Faune Entomologique du Canada, iii, p. 213.

This name is placed by most authors as a synonym of *rimosa*, but we think incorrectly. *Okanagana canadensis* on the whole is a larger species than *rimosa*; it is also blacker with the upper portions especially the tegum adorned with much tomentum, different from the
vestiture of *rimosa*. While the pronotum is usually black edged posteriorly with testaceous, there are occasional specimens in which it is mottled each side with testaceous.

I am indebted to Prof. L. M. Stöhr of Ironside, Quebec, for a long series of this species. On June 21, 1916, he collected a male; in 1917 he collected in all 39 specimens as follows: June 22, 2 males; June 23, 4 males; June 24, 3 males; June 26, 6 males; June 28, 7 males; July 1, 2, male; July 19, male and female; July 22, female; July 26, 5 males, 1 female; July 28, 2 males; July 30, male, and Aug. 15, female. In 1918 he collected ten specimens as follows: June 14, male; June 15, male; June 19, 3 males; June 20, female; June 25, 2 males; July 30, male; July 31, male. In June, 1919, he collected eighteen males and five females. These insects are alike and very black in appearance with the venation of the front wings somewhat thickened. When the wings are closed they show the narrow testaceous hind border of the pronotum, a spot each side at the base of the fore wings, four spots arranged in a semi-circle in front of the X, and the higher parts of the X itself usually touched with testaceous.

Prof. Stöhr writes as follows concerning this species: “It is almost exclusively on pines; I have heard it, however, on cedar trees, and in two instances on willows. Usually it perches at the very extremity of the trees, often only a few inches below the terminal bud, or at the end of the branches. In order to begin the hunting one moves toward the cluster of trees from whence the song seems to proceed. It is, however, difficult to take one’s bearings for the noise now seems to come from the left and now from the right. Conditions still get worse when the suspicious insect suddenly stops its song while one is looking his eyes out in order to locate it, and absolute silence follows the loud clamour. If one has not ascertained with certainty the exact position of the insect he might better try his luck elsewhere, if he does not want to take too many chances. Once a tree found on which an *Okanagan* sits, the ascent begins. When the song has not stopped before, invariably it ceases then, and from the top of the pine one has no other resource than to inspect branch by branch and with good luck one may thus detect the Cicada perched on a twig, the dark color of the bark making it diffi-
male, Davis collection; Sonoma Co., female, Davis collection; Trinity Co., June 6, 1917, female (E. R. Leach); Santa Cruz Co., July, 1917, male (E. R. Leach), Davis collection.

Oregon.—Josephine Co., June 8, 1910, female, and June 9, 1910, male (Nunenmacher), Davis collection.

**Okanaganana arctostaphyloides** Van Duze.

This species was described from four males and one female from Calaveras Co., Calif., 1,800 ft., collected by Dr. F. E. Blaisdell. One of the male cytotypes is now in the U. S. National Museum, and one in the writer’s collection.

The uncus is not hooked at the extremity and so for convenience in identification the insect is considered here, but it and *rubrovenosa*, which has a hooked uncus, closely resembles each other. They are also both rather slender bodied insects. The color of the basal cell, costal margin, veins and membranes, is dull red in both species. In *arctostaphyloides*, however, the body is not as black as in *rubrovenosa*; it has a black band connecting the eyes; a black irregular spot behind the ocelli; sides of the pronotum blackened; collar of the same reddish color as the central part of pronotum; abdomen with a black dorsal vitta, broadest at the base.

**Okanaganana canescens** Van Duze.

The male type of this species came from Sonoma Co., Calif., July 14, 1908, and is in the collection of Dr. F. E. Blaisdell. Mr. Van Duze also had a female from the Bay region of California when he wrote his description.

To these records we can add the following all from California. A male labeled “California,” Am. Museum Natural History; Chico, two males (Dr. E. D. Ball); Alameda, July 12, 1911, male (Nunenmacher), Davis collection; Palo Alto, three males (C. H. Kennedy), Davis collection; Merced Co., two males, June 19, 1914, Davis collection. One of the males from Merced Co., and one from Palo Alto, have been examined by Mr. Van Duze. In the U. S. National Mu-

seum there is a male from Santa Cruz Mts., Calif., that appears to belong to this species. It bears a label “New to Uhler, 1893.” The lighter colors on the head, pronotum and mesonotum are much more extended than usual. The tergum is black; the uncus is the same as in *canescens*.

**Okanaganana viridis** Davis.

This species was described from a male and female from O’Reilly, Mississippi, and so far they are the only specimens known. Its green color and size will serve at the present time to separate this remarkable insect from the other species of the genus.

**Okanaganana aurantiaca** Davis.

The three males and one female from which this orange and black species was described are supposed to have come from Lower California, Mexico. No additional specimens have been seen.

**Okanaganana fratercula** Davis.

This was described from a single male in the collection of the Museum of the Brooklyn Institute of Arts and Sciences, from Iron Co., Utah. The following are additional records: Kolb Mts., Washington Co., Utah, 8,500 ft., June 30, 1917, male (George P. Engelhardt), Davis collection; Nephi, Utah, June 25, 1912, male (Dr. E. D. Ball), Davis collection; Blackfoot, Idaho, June 22, 1904, male (E. S. G. Titus), U. S. National Museum; Springfield, Idaho, July 24, male and female (H. Skinner), Acad. Natural Sciences, Philadelphia; Reno, Nevada, June 6, 1909, two males (Dr. E. D. Ball), Davis collection; Iron Springs, Cedar City, Iron Co., Utah, June 26, 1919, 5,750 ft., three males and twelve females (T. Spalding); Coal Creek, Iron Co., Utah, June 27, 1919, male (T. Spalding), Davis collection. The specimens from Nevada and Iron Co., Utah, may belong to a distinct and larger species with wing expanse as great as 65 mm. They have the front wings beautifully colored. The veins surrounding the marginal cells and first ulnar cell, are very dark, the remaining veins are bright yellow, and the basal cells is blackened. The tergum is blacker than in typical *fratercula*, segments seven and eight being the only
ones edged with orange on dorsum; valve yellow. The female from Springfield mentioned above is like the male type with which it has been compared, except that it expands 58 mm. instead of 46. The shape of the head and colors are the same. The last ventral segment shows a slight indication of a double notch.

Okanagana oregonus Davis.

The original description was from the type, allotype, and thirteen other specimen, all from Oregon. Additional records are: Wren, Oregon, July 4, 1905, male; East Toll Gate, Oregon, July 15, 1906, female, and Mayville, Oregon, July 15, male, all from Prof. A. L. Lovett, and in the collection of the Oregon Agri. College. Mt. Moscow, Latah Co., Idaho, 5,000 ft., two males (T. Magee), from Prof. A. C. Burrell, Univ. of Idaho. Bridger Canyon, Gallatin Co., Montana, July 7, 1904, female, from Prof. R. A. Cooley, and in the collection of the Montana Agri. Experiment Station.

The venation in the wings of this small species is yellowish in color, and the wings are proportionately narrower than in the preceding species.

Okanagana triangulata Davis.

This species was described from a male collected in Mendocino Co., California, and a female in the collection of the American Museum of Natural History from Angel Island near San Francisco was cited as probably of the same species. Mr. G. R. Pilate has sent to me from Olancho, Inyo Co., California, 88 males and 84 females collected June 25, 1917, that agree with the type. They were very numerous at that time on the grass of the Olancho meadows, and Mr. Pilate states that his fingers became quite sticky from some alkaline substance that adhered to the insects as they crawled from the soil. While this species and oregonus resemble each other, they may be separated by the characters given in the table, which appear to be constant for the long series examined. Four males have recently been received from Ukiah, Mendocino Co., California, May, 1919 (E. P. Hewlett).
This is a small species a little larger than *synodica*, with the wings not quite as transparent as usual, which is also the case in *synodica*.

Head not quite as broad as the front margin of the pronotum; front rather prominent. Median suture of the front well defined. Pronotum with the humeral angles rounded and the anterior angles rather prominent. Last ventral segment with the base about as long as the sides, which gradually converge to the truncate extremity. Uncus when viewed in profile situated

but not hooked at the end; when viewed from above evenly curved and narrowed to the extremity which is notched. The last ventral segment in the female allotype is doubly notched. Ventilation of both pairs of wings yellowish, the costal margin of the fore wings a little darker than the radial cell; basal cell yellowish and translucent. The membranes at the base of both pairs of wings are orange-red in color. Dorsum partly clothed with short golden hairs especially on the abdomen along the posterior margin of the segments; beneath the pubescence is short. Head black with all of the grooves and supra-antennal plates testaceous, beneath black in the region of the transverse rugae, which are margined with testaceous; rostrum pale at base. Pronotum black variegated each side, especially in the grooves with pale, and margined all around, except for a short space at humeral angles with testaceous. Mesonotum black, with the hind margin, the elevated X, two spots at the anterior extremities of the X, and the posterior part of the W-mark, testaceous. Metanotum black, posteriorly margined with testaceous. Tergum black, the segments narrowly edged posteriorly with testaceous. Uncus black with a dorsal pale stripe. Beneath pale, including the valve; the usual black spot at the base of the abdomen; legs pale, femora darkened.

*Okanagana balli* looks something like a small *rimosa*, but is more yellow in color, and the transverse fold crossing the fore wings at the node is sometimes developed, as it is in *synodica*.

The first specimen I examined of this species came from Dr. O. S. Westcott, Oak Park, Ill., but was without locality or date label. In the U. S. National Museum there is a female labeled Winona, Minn., and in the Uhler collection in the same museum, there is a male from Greene Co., Iowa, labeled "Tibicen n. sp., Stal." In Prof. Albert P. Morse’s collection there is a male labeled Little Rock, Iowa, and Dr. E. D. Ball has sent me fifteen males and one female from Little Rock, Iowa. It is evident that at the time they were collected they appeared as a swarm, but unfortunately they bear no date. In the collection of the University of Minnesota there is a male labeled Rock Co., Minn., June 24, 1910, and four other males without locality labels. In the collection of the South Dakota State College, there are five males and two females labeled Brookings, S. D., and a male and female labeled S. D. These and the specimens mentioned above closely resemble one another in size and markings.

*Okanagana rubrovenosa* Davis.

The following records are additional to those given in the original description: Sonoma Co., Calif., July 4, male (O. Sack), U. S. Nat. Museum. The label further states, “Its note is continuous (not intermittent) and not loud. It resembles the whirring of a bee in confinement.” Hullville, Lake Co., Calif., June 13, 1917, two males, three females (Dr. F. E. Blaisdell). Ukiah, Calif., May, 1919, three males (E. P. Hewlett). Keddie, Plumas Co., Calif., 3,500 ft., June 24, 1918, two males, and June 28, 1918, male and female (Frank M. Jones). In transmitting these specimens and a twig in which a cicada had oviposited, Mr. Jones writes: “The red cicada, of which there are four examples, was locally abundant and in constant song in the manzanita bushes, and the manzanita twig showing egg-deposit almost certainly belongs to this species, though I did not see the female at work.”

The female of this beautiful insect has never been described. The one collected by Mr. Jones expands 64 millimeters and is of the same color as the type; the body black above covered with short reddish
hairs, which gives it a rusty appearance. The tergum is black where denuded of hair. Beneath the abdomen is densely clothed with hair, black in color with the hind margin of the segments dark red. The notch in the last ventral segment is double. There are the same patches of silvery hairs at the base of the fore wings as in the type. The three females received from Dr. Blaisdell are like the one just described, except that they are a little smaller.

Okanagana vanduzeei Distant.

The type locality for vanduzeei and what are here considered as two varieties of that species, is San Diego Co., California.

Through the kindness of Prof. Wm. S. Wright I have received 86 males and 9 females of vanduzeei; 25 males and 12 females of var. consobrina and 2 males of var. californica collected at Dulzura, San Diego Co., Calif., from June 12 to 25, 1917. Prof. Wright considered that he had collected in this long series but one species, and describes its song as follows: "It is low, long continued and sweet. They will sing for nearly half an hour without a quaver; they usually are to be found setting high up in the brush, seldom in the trees."

In addition to the specimens already mentioned the following have been examined, and unless otherwise stated they are in the writer's collection.

San Diego, Calif., May 6, 1916, twelve males, two females (Prof. Wm. S. Wright); San Diego, Calif., June 25, 1914, two males determined as vanduzeei and collected by Mr. Van Duzee; Santa Catalina Island, June, 1917, male; Santa Rosa Island, male, collection Am. Museum Nat. History; Los Angeles, Calif., June 10, 1916, male (A. C. Davis); San Jose, Calif., July 4, four males (King), collection Dr. E. D. Ball; Alameda Co., Calif., June 29, 1914, nine males, June 30, 1914, thirty-four males and two females (F. W. Nunenmacher); Piedmont, Alameda Co., Calif., July 22, 1912, two males, May 18, 1917, male, and July 2, 1917, eight males (Nunenmacher); Contra Costa Co., Calif., June, male; Keddie, Plumas Co., Calif., 3,500 ft., June 26, 1918, male (F. M. Jones); Oroville, Calif., July 24, 1912, male (E. D. Ball), collection Dr. Ball; Lassen Co., Calif., June 5.

1913, female (Nunenmacher); Twin Falls, Snake River Canyon, Idaho, July 6, 1917, female (Mrs. A. C. Burrill). Mr. Van Duzee has recorded this species as far north as Mt. Rainier, Washington.

Mr. E. R. Leach has sent to me the following specimens of a small form of vanduzeei expanding from 50 to 55 millimeters: Trinity Co., Calif., July 18, 1917, two males, one female, and June 17, 1918, two females.

Of variety consobrina the following have been examined: San Diego Co., Calif., May 22, 1914, three males; May 23, 1914, one male; May 24, 1914, two males (E. P. Van Duzee). La Jolla, San Diego Co., Calif., June, 1916, six males and a female; August 1, 1917, one male (Geo. P. Engelhardt). Santa Monica, Los Angeles Co., Calif., May 28, 1916, male and two females (A. C. Davis), Los Angeles Co., Calif., July 8, 1916, male; Pasadena, Calif., July, 1917, male, and May, 1918, two males (Alonzo C. Davis). Santa Barbara, July 7, 1907, two males (Prof. Jas. S. Hine); San Jose, Calif., July 4, two males, one female (King), collection Dr. E. D. Ball; Polo Alto, Calif., male (C. H. Kennedy); Whitebird, Idaho, June 28, 1907, female (Dr. J. M. Aldrich). Two of the San Diego specimens have been identified as consobrina by Mr. Van Duzee, and several of the seven individuals from La Jolla approach typical vanduzeei.

Of variety californica the following have been examined: San Diego Co., Calif., July 9, 1913, male, collected and determined by Mr. Van Duzee; July 12, 1913, eight males; Aug. 3, 1913, one male (Prof. W. S. Wright); August, male, came to light. Pasadena, Calif., July 2, 1917, male (A. C. Davis).

In the JOURNAL OF THE N. Y. ENTO. SOC., March, 1915, Mr. Van Duzee suggests that californica may be a variety of vanduzeei, rather than a separate species as originally described.

Okanagana striatipes (Haldeman).

1852. Stansbury's Exploration and Survey of the Valley of the Great Salt Lake of Utah, p. 369, pl. 9, fig. 16.

No definite type locality is mentioned by Haldeman in the original description, which calls for an insect expanding 52 millimeters, with a prominent face; beneath yellow, end of rostrum, a few points near the joints of the feet and a transverse line at the base of the abdomen, black. The tergum is black with the margins of the segments yellow.
This is not an uncommon species in Utah, and neighboring states, and the following specimens have been examined: Honeyville, Boxelder Co., Utah, 1907, female (E. G. Titus), and Logan, Cache Co., Utah, July 13, 1907, male, collection Dr. E. D. Ball. Promontory Pt., Great Salt Lake, Utah, July 11, 1911, male (Dr. J. M. Aldrich), collection University of Idaho; Salt Lake City, Utah, male (Dr. Henry Skinner), Acad. Nat. Sci. Philadelphia; Stockton, Utah, July, 1913, two males; July, 1914, four males; July, 1915, female; Sept. 2, 1916, four males, all collected by Tom Spalding and in Davis collection. South Creek, Beaver Co., Utah, two males (Engelhardt), Davis collection. Cedar Creek, Iron Co., Utah, 5,500 ft., July 9, 1917, seven males (G. P. Engelhardt); Bellevue, Washington Co., Utah, 4,500 ft., June, 1917, and July 7, 1917 (G. P. Engelhardt), Davis collection. Kanab, Kane Co., Utah, June 24, 1913, two males, collection Dr. E. D. Ball. Flagstaff, Arizona, June 29, 1892, two males, Davis collection. In Mr. Van Duze's Catalogue of Hemiptera, California and Oregon are also given as localities.

Okanagana utahensis new species. Pl. xx, fig. 4.

Type male from Cedar Creek, Iron Co., Utah, 5,500 ft., July 9, 1917 (Geo. P. Engelhardt), Davis collection.

Allotype female from Stockton, Utah, July, 1914 (Tom Spalding), Davis collection.

Resembles striatipes, but is larger and darker colored, and the vestiture of the pronotum and mesonotum is not an appressed pubescence as in that species, but contains many long silvery hairs.

---

Head about as broad as the front margin of the pronotum; front more protruding than in most species of the genus; median sulcus well defined. Pronotum with the humeral angles rounded and the anterior angles prominent. Last ventral segment constricted at the sides, then broadened out to the extremity, which has the outer angles rounded and a sinus centrally. Uncus when viewed in profile hooked at the end; when viewed from behind, the book is seen to be notched. The last ventral segment in the female allotype is rather deeply notched. Venation of the fore wings testaceous, darker beyond the transverse fold. Costal margin of fore wing yellow to end radial cell, darker beyond; subcostal vein black, or nearly so in some of the paratypes; basal cell clouded, in some of the paratypes blackened; the vein (C2) on the inner side of the eighth marginal cell is usually light in color. Both pairs of wings variegated with black at base, with the membranes orange-red. Dorsum partly clothed with short silvery hairs, which are rather long in the cavities about the mesonotal X; in striatipes the hairs are short about the X and more golden in color. Beneath the vestiture is abundant, but the hairs are not long. Head black with the grooves and supra-antennal plates testaceous; beneath with the median sulcus orange; the transverse rugae black; rostrum black, orange at base. Pronotum black, the grooves testaceous; bordered all around with orange, but more narrowly on the anterior margin. Mesonotum black, with the hind margin orange; the elevated X orange, variegated with black, and four orange spots arranged in a semicircle in front of the X. Metanotum black, posteriorly margined with orange. Tergum black the eighth and ninth segments margined posteriorly with orange. Uncus black; in some of the paratypes there is a dorsal pale stripe. Beneath, black, the legs pale striped with black, and each abdominal segment edged posteriorly and on the sides with orange. In the allotype and some of the paratypes the black is reduced to an interrupted stripe on the central part of the abdomen, with a black spot each side on the segments. Valve pale variegated with black.

In addition to the type and allotype the following specimens have been examined, and unless otherwise stated, they are in the writer's collection.

Utah.—Logan, Cache Co., June 28, 1904, male, and male, July 13, 1907, collection Dr. E. D. Ball. Hyrum, Cache Co., July 27, 1904, two males, collection Dr. E. D. Ball. Wellsville, Cache Co., Utah,

Arizona.—Tuba, June, 1913, six males and one female (Dwight Franklin).

Idaho.—Payette, Canyon Co., male (Vastal), and Glenn's Ferry, Elmore Co., 1904, two males (Ewing), collection Oregon Agri. College.

Washington.—Logie Creek, Yakima Co., June 16, 1916, two males (C. H. Kennedy). Of these two males Mr. Kennedy writes, "they are from sage bushes and are a true desert species. They have a long shrill call, are shy, and hard to approach."

Okanagana hesperia (Uhler).

Uhler states that his type was collected in the vicinity of Denver City, Colorado, by Cyrus Thomas.

This species has been placed in the same genus with Tibicenoides cupro-sparus (Uhler), but it has the marginal cells of the fore wings more nearly of the length of the ulnar cells as in Okanagana generally, whereas in Tibicenoides cupro-sparus the marginal cells are quite short. The following have been examined:

Colorado.—Denver, July 13, 1909, male; July 14, 1909, male, and July 16, 1909, three males (W. J. Gerhard), Davis collection. Denver, July 27, 1912, male, and June 10, 1913, female (Oslar), Davis collection. Golden, July, male and female (Oslar); July 18, 1909, male (W. J. Gerhard), Davis collection. Fort Collins, June 28, 1900, three males, and July 16, 1903, female, collection University of Kansas; June 28, 1900, three males, three females, and July 17, 1900, five males, collection Dr. E. D. Ball; July 16, 1903, male (Van Duzee), Davis collection. Fort Collins, Jefferson Co., July, two males (Oslar), Davis collection. La Junta, Otero Co., two males (Oslar), Davis collection. Trinidad, Las Animas Co., July 15, 1910, female, and male and female without date (Oslar), Davis collection.

Kans.—Trego Co., 2,450 ft., July 12, 1912, five males, one female; July 13, 1912, three males; July 17, 1912, male (F. X. Williams), collection University of Kansas.

New Mexico.—Albuquerque, male (Oslar); Silver City, male; Jemez Springs, 6,400 ft., June 28, 1918, male, June 24, 1919, female (John Woodgate), all in Davis collection.

Montana.—Billings, July 16, 1904, male; Custer, Aug. 1, 1912, male, and Miles City, July 1, 1915, three males, collection Montana Agri. Exp. Station.

Okanagana pallidula Davis.

Only the type and nine paratypic males have been examined, all collected at Athlone, Merced Co., California, in July and August, 1917, by Alonzo C. Davis, as recorded in the original description.

Okanagana uncinata Van Duzee.

The type locality for this species is Orange Co., California. Mr. Van Duzee has kindly sent me the type for examination, and also given me a paratype.
Okanagana mercedita Davis.

Only the type, the allotype and 16 males and 14 females from Merced Co., California, June 18, 1914, have been examined.

The short marginal cells in the fore and hind wings of this species, also in O. minuta and Tibicinoides cupreo-sparsus suggest a close relationship, and we think that they will ultimately be associated in the same genus. The supplementary transverse veins at the node are also more developed in mercedita and minuta than in most species of Okanagana, though not quite as well defined as in cupreo-sparsus, the type of the genus Tibicinoides.

Okanagana minuta Davis.

The original description was based on the type and 11 paratype males, all from Sanford University, California, May 26, 1914 (C. H. Kennedy), and a female, Fresno Co., California (J. C. Bradley). Mr. Alonzo C. Davis has sent me three males collected at Lebec, Kern Co., Calif., June, 1918.

Tibicinoides cupreo-sparsus (Uhler).

This small, beautiful, black and red species has been included in the table as an aid to the identification of species, and as has already been stated, probably Okanagana mercedita and O. minuta should be transferred to the genus Tibicinoides. The types mentioned by Uhler were two females captured near Los Angeles, California, by D. W. Coquillett.

The following specimens are in the writer's collection, all from southern California: San Diego Co., May 6, 1914, two males, and May 24, 1914, three males (E. P. Van Duzez); San Diego, July, 1914, three males (Prof. W. S. Wright); La Jolla, June 6, 1915, three males (B. B. Fulton); Dulzura, San Diego Co., June 13-21, 1917, twenty males (Prof. W. S. Wright). In the collection of Dr. E. D. Ball, there is a male collected at Ontario, San Bernardino Co., June 12, 1908.

In the Transactions of the San Diego Society of Natural History, Vol. 2, p. 48, November, 1914, Mr. Van Duzez comments on this species as follows: "This very pretty little species was abundant this season from April 26th until nearly the first of June. It occurs almost exclusively on a certain fine tufted grass, probably a Poa, growing on the hillsides about La Jolla and up Mission Valley and adjacent canyons as far as the Old Mission and perhaps farther. The bright red on the base of the wings gives this species a lively appearance when spread. Like hesperia Uhler it has the basal one half of the elytra infuscated. It has a shrill but feeble note which is long continued and easy to locate, but can rarely be heard for more than one hundred feet."

Okanagodes new genus.

In this genus the uncus is exposed as in Okanagana and the valve and wing venation are the same, but the pronotum is much narrower behind the eyes and the latter are exceedingly prominent. The front protrudes considerably and the supra-antennal plates are also prominent. The body is slim with the sides more parallel than in any known species of Okanagana. The type of the genus is the new species described below and figured on the accompanying plate.

Okanagodes gracilis new species. Pl. xx, fig. 6.

Type male and allotype female from Washington Co., Utah (Weidt). Davis collection.

A slim species the body in size about as in Okanagana synodica, but the sides are more parallel and the wings are proportionately longer. Eyes vary prominent; fore part of pronotum considerably narrowed. The front is also very prominent with the median sulcus at first indistinct but lower down well developed; the supra-antennal plates are much enlarged. The result of these characters is to give the front of the head, when seen from above, a more uneven outline than in any Okanagana studied. The hook at the end of the
uncus is not much bent and it has no terminal notch. The opercula are small and the song apparatus plainly exposed. The comparatively few hairs on the underside of the abdomen are short and light colored; the last ventral segment is pubescent, constricted at the sides and rounded at the extremity. The insect is almost wholly straw-colored covered with a whitish pubescence; the eyes are darker and the ocelli are large and ruby colored. The transverse rugae are darkened; there is an inverted V-shaped mark on the front between the supra-antennal plates. Pronotum with a dark-colored hour-glass-shaped spot centrally; the grooves darkened, and the posterior margin light-colored. Mesonotum with four cuneiform dark spots stretching backward from the anterior margin, the inner pair (the W-mark) not as long as the outer pair. A dark line extending from the base of each fore wing backward to the elevated X; two small dark spots at the anterior extremities of the X. Metanotum with a small dark elongate spot near the base of each hind wing and a more rounded one above each tympanum. Abdomen with the segments darkened at the base, but not on the sides. The costal margin of the fore wings straw-colored to the end of the radial cell, darkened beyond, the remaining veins and about the outer half of the wing also darkened. Basal cell clear. The anal membranes of the fore and hind wings are whitish, those of the hind wings include a clouded spot. Beneath there is a small elongate shining black spot each side near the base of the rostrum, which itself is blackened at the extremity. There is a dark spot at the base of each wing and dark lines at the base of the legs; the claws and spines of the legs also darkened. The usual dark spot centrally at the base of the abdomen. The allotype is colored as in the type except that there is a small dark spot at the side on each abdominal segment from the third to the seventh, and also a fainter one not in line with the others on segment eight. The notch in the last ventral segment is simple.

In addition to the type and allotype another male and female from the same locality and without date, are in the writer's collection, as is also a male from Maricopa, Pinal Co., Arizona, July 3, 1918, collected by A. M. Gaudin. This last has the body almost wholly straw-colored and shows but faintly or not at all the darker marks described in the type. In the collection of the Bureau of the Biological Survey, U. S. Department of Agriculture, there are eighteen males and five females, collected at Higley, Arizona, July 17 to 25, 1917, by E. G.
Holt. This series has individuals marked as in the type and others that are almost wholly straw-colored.

Several of the species of the allied genus *Clidophleps*, which comes next in the catalogue, were figured in the *Journal of the N. Y. Entomological Society*, March, 1917.
